Code/Config changes performed:

App Architecture:

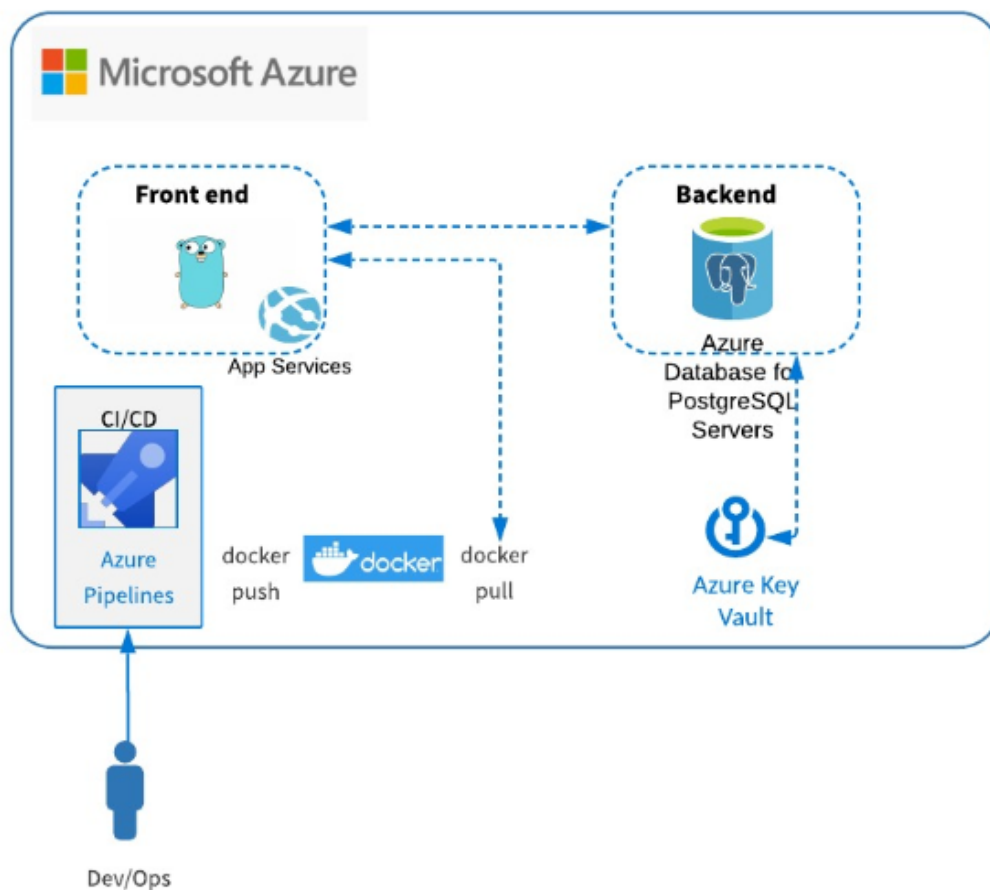

Tech stack given :

Source Code Git:

<https://github.com/servian/TechChallengeApp>

Frontend	SPA Written in GoLang
Backend	PostgreSQL

Proposed Architecture:

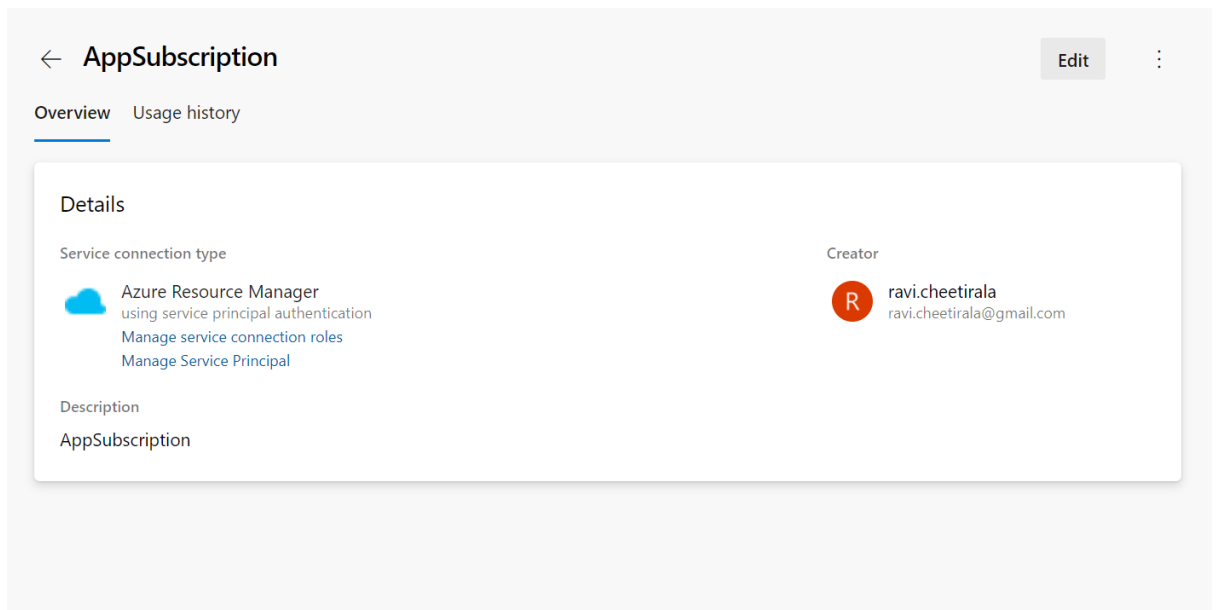

- The front end of the application is deployed in Azure App Service using the docker container.
- The Database of the application is deployed in Azure Database for PostgreSQL servers
- Both App Service and PostgreSQL are the PaaS Services.
- CI/CD Pipeline is created to install both the Database and App Service ,along with the required configuration.
- App Service parameter file is hardcoded with the Docker image(318300/servianapp)

- There is No separate build pipeline is created to build the docker image

CI/CD:

Pre-Requisites:

- Create a service connection with the name “AppSubscription” to connect to the subscription.

Note: We would need to create a Service Principal for the subscription to connect to the subscription from Azure DevOps assuming both Azure devops and App Subscription are different

- Create a keyvault with the below CLI commands
 - `az keyvault create --name raviservianappkv --resource-group ServianAssignmentRG --location "Australia East"`
 - `az keyvault secret set --name dbpassword --vault-name raviservianappkv --value *****`
- Create variable group in Azure DevOps to fetch the secrets from the key vault in the pipeline

☒ Link secrets from an Azure key vault as variables ⓘ

Delete	Secret name	Content type	Status	Expiration date
	dbpassword		Enabled	Never

- ARM templates are created for all the required resources and available under the ARMTemplates folder ,which is under the root folder of the application.

arm_appservice.parameters.json	Update arm_appservice.parameters.json	1 hour ago
arm_azurepostgresql.json	Create arm_azurepostgresql.json	1 hour ago
arm_azurepostgresql.parameters.json	Update arm_azurepostgresql.parameters.json	32 seconds ago

Executing the app:

- Import the Github project in Azure Devops project
- Create the pipeline using the existing pipeline.yml(azure-pipelines.yml) ,which is available under the root folder of the repo.
- Trigger the pipeline manually,once the pipeline complete, please navigate to below url in browser
 - <https://raviserviantechassignmentapp.azurewebsites.net/>

Code/Config changes performed:

- Dockerfile is updated to add the port number and entrypoint is updated.
 - RUN echo "./TechChallengeApp updatedb; ./TechChallengeApp serve" > trigger.sh
 - EXPOSE 8080
 - ENTRYPOINT ["/bin/sh", "trigger.sh"]

- Conf.toml is updated with the below connection details.
 - "DbUser" = "servianappuser@ravixrca4postgresql"
 - "DbPassword" = "<keyvault key>"
 - "DbName" = "serviandb"
 - "DbPort" = "5432"
 - "DbHost" = "ravixrca4postgresql.postgres.database.azure.com"
 - "ListenHost" = "0.0.0.0"
 - "ListenPort" = "8080"
 - "sslmode" = "require"

- Db.go is updated as the AzurePostSQLDB creates the user with user@servername, while the database creation is failing with that name convention, to avoid that, the owner is hardcoded and the same is being created in the CI/CD process. Also the table_namespace is not required to be given in the latest versions of DB.
- Docker image is in my public docker hub repo with name "318300/servianapp"

Some of the improvements to be/can be done:

- In the given solution, database is open for all the azure resources, which can be avoided by creating a private endpoints /vnet
- App Service is also not restricted to the world, any user through the internet can be accessed ,which can be avoided by an isolated SKU/ASE
- ARM template can be extended to run the scripts instead of a separate CLI task.
- Parameterisation of the data.
